Smarti Environmental CRM

Project summary

What I built

A simple web CRM built with React, FastAPI and SQLite. Office staff add customers, track their onboarding, book appointments with fitters and maintenance engineers, and follow each job to completion. An appointment and its job share one record, so each booking is entered once.

What I am most pleased with

The steps connect into one workflow, from first enquiry to maintenance visit. Booking a job moves a customer from New Enquiry to In Progress, completing it makes them Active, and the customer's page says what to do next. The Overview page shows new enquiries, overdue jobs and each staff member's workload.

Before choosing the server technology, I built the same small feature four ways, which exposed problems the final design avoids. The server code has 133 automated tests, and when I broke each onboarding rule on purpose, a test failed every time.

What I would improve next

- Login and roles, so fitters and engineers can see their jobs and update them on site.
- Job durations, to catch overlapping bookings as well as exact clashes.
- A Cancelled status, notes on completed jobs and a duplicate-customer check.
